Do nanostructures have electromagnetic energy storage and power dissipation? Nanostructures have the capability for electromagnetic energy storage and power dissipation, with both the materials properties and the structure geometry playing important roles. Do nanogratings have local energy storage and power dissipation density? The local energy storage and power dissipation density in the nanogratings are investigated using the RCWA method. This information helps to understand the geometric effect on the global radiative properties of nanogratings. How does energy density affect energy storage? For energy storage, the energy density relates the stored energy to the volume of the storage equipment, e.g. the fuel tank. The higher the energy density of the fuel, the more energy may be stored or transported for the same amount of volume. The energy of a fuel per unit mass is called its specific energy. Do materials optical properties affect energy storage and power dissipation density? The optical property of materials has been studied by many researchers in relation to energy storage and power dissipation density. Early works on this topic were conducted by Loudon, Barash, Ginzburg, Brillouin, and Landau, among others. More recent studies have been carried out by Ruppin, Shin et al., and Vorobyev. Is power dissipation related to energy storage? Both power dissipation and energy storage are related, since electric and magnetic fields can store energy. However, for nonmagnetic materials, only electric current can result in power dissipation. Understanding this relationship may offer deep insight into the radiative properties of nanostructures. What is the energy density of a magnetic field? H as the 2 energy density, that is, energy per unit volume stored locally in the magnetic field. current changes the magnetization is volume integral of $\int H \cdot dB$. However, this energy is not all recovered when the B returns to its initial value because the path of integration is different. No single energy storage method boasts the best in specific power, specific energy, and energy density. Peukert's law describes how the amount of useful energy that can be obtained (for a lead-acid cell) depends on how quickly it is pulled out.
