How does crystal structure determine electrochemical energy storage characteristics? Abstract Crystal structure determines electrochemical energy storage characteristics; this is the underlying logic of material design. To date, hundreds of electrode materials have been developed to pursue superior performance. Does crystal packing density affect energy storage performance? We then present and classify the typical crystal structures of attractive cathode/anode materials. Comparative PF analyses of different materials, including polymorphs, isomorphs, and others, are performed to clarify the influence of crystal packing density on energy storage performance through electronic and ionic conductivities. How does Crystal PF affect the electrochemical performance of energy storage materials? As discussed with respect to polymorphs, isomorphs, and materials with various anions, crystal PF has a substantial influence on the electrochemical performance of energy storage materials, which is of great significance for understanding the differences between many materials and for guiding modification strategies. What are electrochemical energy storage materials? In summary, electrochemical energy storage materials are the key components of energy storage devices, with properties determined to a large extent by their intrinsic crystal structure; this is the underlying logic of material design. Can a nonferroelectric molecular crystal utilise light as an external stimulus? However, it is challenging to realise nano-scale energy storage and conversion in the same material. Here the authors report a nonferroelectric molecular [CoGa] crystal that uses light as an external stimulus to exhibit photoenergy conversion and energy storage properties. What are energy storage materials? Energy storage materials such as capacitors are made from materials with attractive dielectric properties, mainly the ability to store, charge, and discharge electricity. In the realm of crystals, the potential to store energy is encapsulated in a process known as 'reversible electrochemistry', where the energy is not lost but rather retained within the crystal's structure for future use (UCSUSA).
