Latent heat storage systems use the reversible enthalpy change  $Dh_{pc}$  of a material (the phase change material = PCM) that undergoes a phase change to store or release energy. Fundamental to latent heat storage is the high energy density near the phase change temperature  $t_{pc}$  of the storage. Latent heat storages utilise the absorption and release of heat at a constant temperature level during a phase change, usually from solid to liquid and vice versa. Compared to sensible storages, the energy density of latent heat storage materials (PCM = phase change material) is significantly higher, emphasizing their distinct insights based on the specific application. LHTES systems address the escalating demand for efficient and environmentally friendly energy management across various sectors. These systems leverage Phase Change Materials (PCMs) to store and release thermal energy. A phase change material (PCM) is a high latent heat material that can be used to store thermal energy and regulate local temperatures. In buildings, PCMs can be used to mitigate and time-shift thermal load peaks by absorbing heat gain during warmer daytime via melting and releasing the stored energy. What is Latent Heat Storage In comparison to sensible heat storage systems, the latent heat storage has the advantages of high storage density (due to high latent heat of fusion) and the isothermal nature of the storage process.
